We study in this paper the direct interband transitions in a quantum dot superlattice system. We obtain the analytical expressions for the light interband absorption coefficient and threshold frequency of absorption as the functions of geometrical size of quantum dot superlattice system. According to the results obtained from the present work, we find that the absorption threshold frequency decreases when the size of quantum dot superlattice increases.

Keywords: Absorption coefficient, interband transition, quantum wells, quantum wires, quantum dots, superlattices, quantum dot superlattice

Over the last decades, there has been considerable interest in low-dimensional semiconductor systems in which the electron motion is strongly confined such as quantum wires, quantum dots, etc. Low-dimensional semiconductor structures include quantum wells, quantum wires, quantum dots, superlattices, and so on. Since in the systems one, two or three of the dimensions become of the order of the de Broglie wavelength for electrons, new quantum effects are expected [1].

Low-dimensional semiconductor structures, particularly quantum dots are attracting considerable attention recently, in part, because they exhibit novel physical properties and also with potential and real applications in many electronic and optoelectronic devices. In the last decades, a modern technologies, in particular such as Stranski-Krastanov epitaxial method have been developed to grow a wide variety of quantum dots structures having different geometries (spherical, parabolic, cylindrical and rectangular) and potentials (parabolic potential model, the square well model) [2-4].

Recent interest to semiconductor quantum dots is conditioned by new physical properties of these zero dimensional objects, which are conditioned by size-quantization effect of the charge carriers [5-7]. The presence of size quantization in all three directions makes the energy spectrum of charge carriers and strongly dependent on the geometry and linear dimensions of the sample [3]. It is clear that the more geometrical parameters characterize quantum dot, the more exibly one can control its energy spectrum. The subject of quantum dots as low-dimensional quantum systems has been the focus of extensive theoretical investigations. Much effort has recently been done in understanding their electronic, optical and magnetic properties.

In the last few years there has been considerable theoretical and experimental study has been carried out on the electronic and optical properties of multiple quantum well heterostructures. The central motivation of such studies has been the possible applications of these systems in optoelectronic devices. Growth techniques, such as molecular-beam epitaxial and metal-organic chemical vapor deposition, have made possible the fabrication of highly pure structures with abrupt interfaces, allowing for the tailoring of the electronic structure to suit almost any need. An interesting example is thevariably spaced semiconductor superlattice [8].

Quantum dot superlattices are hence expected to display radically different non-equilibrium transport properties than quantum well superlattices. Potential applications for high performance thermoelectric converters [9], photovoltaics[10], and quantum cascade lasers [11] further motivates the fundamental understanding of the nonequilibrium transport properties of superlattices with 3D quantum confinement.

Quantum dot superlattice structures, which have a delta-function distribution of density of states and discrete energy levels due to three-dimensional quantum confinement, a potentially more favorable carrier scattering mechanism, and a much lower lattice thermal conductivity, provide the potential for better thermoelectric devices [12].

As we know, the study of the optical properties of low-dimensional semiconductor structures is important, not only to know, but also in the fabrication and subsequent working of electronic and optical devices based on such systems. There are many theoretical and experimental works on the optical properties of nanostructures such as quantum dots, quantum wires, and quantum wells [13-21]. The optical properties of low-dimensional semiconductor systems are especially useful in giving detailed information about their microscopic physics. One of the interesting optical properties is the light interband absorption coefficient. The spectroscopy of optical transitions across the band gap (interband transitions) is a powerful and versatile method to study the electronic structure of semiconductors. The optical properties of quantum dot for the first time were considered by Efros and Efros [4] at theoretical investigation of direct light absorption in spherical quantum dot with indefinitely high walls. Lipovskii [22] discussed the influence of anisotropy of band structure on optical transitions in spherical quantum dots.

Even though considerable attention has been given to the study of the light interband absorption of the semiconductor quantum dots superlattice structures.

The light interband absorption of quantum dot superlattice structures has not been investigated so far. In the present work, we study the interband light absorption in a quantum dot superlattice structures. We obtain the light interband absorption coefficient and show dependencies of the absorption threshold frequency and on geometrical size of quantum dot superlattice structures.

The interband absorption in a quantum dot superlattice with a periodic potential $U(z)$ of period $d$.

$$H = \frac{p^2_z + p^2_y}{2m^*} + m^* \left( \omega_x^2 x^2 + \omega_y^2 y^2 \right) + \frac{\Delta}{2} \left( 1 - \cos \frac{p_x d}{\hbar} \right),$$

where $\Delta$ is the miniband width. The electron effective mass $m^* = m_e$, when the conduction band is considered; and $m^* = m_h$ when the valence band is considered, where $m_h$ is the effective mass of the hole.

$$V(x, y) = \frac{m^*}{2} \left( \omega_x^2 x^2 + \omega_y^2 y^2 \right),$$

along the $z$-direction of the harmonic oscillator form is considered:

$$E_{n,l,k}(z) = (n + \frac{1}{2}) \hbar \omega_x + (l + \frac{1}{2}) \hbar \omega_y + \frac{\Delta}{2} \left( 1 - \cos \frac{p_z d}{\hbar} \right),$$

where $n(=0,1,2,\ldots)$ and $l(=0,1,2,\ldots)$ are the level indices of the electronic subbands, $k$ is the component of the wave vector in the $z$-direction, $\Psi_n(x), \Psi_l(y)$ are the eigenwave functions of the harmonic oscillator, $H_n(x), H_l(y)$ is the Hermite polynomial, $l_x = \sqrt{\hbar/(m^* \omega_x)}, \quad l_y = \sqrt{\hbar/(m^* \omega_y)}$.

$$\Psi_{n,l,k}(x) = \frac{1}{\sqrt{L_z}} \Psi_n(x) \Psi_l(y) \xi_{l,k}^*(z),$$

$$\xi_{l,k}^*(z)$$ is the Bloch function in the approximation of strong coupling in the $z$-direction, and $L_z$ is the normalized length in the direction.

The eigenwave functions of the harmonic oscillator for the conduction band are set,

$$_{\text{conduction band}}$$

$$\Psi_{n,l,k}(x) = \frac{1}{\sqrt{L_x}} \Theta_n^{l_x} \exp[-x^2/2L_x^2] H_n \left( \frac{x}{l_x} \right),$$

$$\Psi_{l,l,k}(y) = \frac{1}{\sqrt{L_y}} \Theta_l^{l_y} \exp[-y^2/2L_y^2] H_l \left( \frac{y}{l_y} \right),$$

The eigenwave functions of the harmonic oscillator for the valence band can be expressed as

$$_{\text{valence band}}$$

$$\Psi_{n,l,k}(x) = \frac{1}{\sqrt{L_x}} \Theta_n^{l_x} \exp[-x^2/2L_x^2] H_n \left( \frac{x}{l_x} \right),$$

$$\Psi_{l,l,k}(y) = \frac{1}{\sqrt{L_y}} \Theta_l^{l_y} \exp[-y^2/2L_y^2] H_l \left( \frac{y}{l_y} \right)$$
Expressions Eqs (3) - (8) show the charge carriers energy spectrum and wave functions in quantum dot superlattice system. These relations allow to calculate the direct interband light absorption coefficient in quantum dot superlattice system.

Since in the future we will consider transitions in the quantum dot superlattice, where instead of quasicontinuous bands of the energy spectrum we have a set of discrete energy values, it follows that after integration, we should proceed to summation over quantum numbers. As a result, the equation for the absorption coefficient of a quantum dot superlattice can be expressed by [4]:

\[
K(\Omega) = A_0 \sum_{v',v} \left| \psi' \psi_d^* \right|^2 \int dV \delta[\Omega - E_v^d - E_v^e]
\]

where \(A_0\) is the quantity proportional to the square of dipole moment matrix element modulus, taken on Bloch functions.

The \(\sum_{v',v} \left| \psi' \psi_d^* \right|^2 \int dV\) can be obtained using following expressions

\[
J_{n,n_0} = \int_{-\infty}^{\infty} \Psi_{n_0} \left( \frac{x}{l_x} \right) \Psi_{n} \left( \frac{x}{l_x} \right) dx
\]

\[
J_{l,l_h} = \int_{-\infty}^{\infty} \Psi_{l} \left( \frac{x}{l_y} \right) \Psi_{l_h} \left( \frac{x}{l_y} \right) dy
\]

where \(J_{n,n_0}\) and \(J_{l,l_h}\) are overlap integrals between the valence and conduction bands.

From Eqs. (9)-(10) it follows that quantum numbers \(n, n'\) can change arbitrarily. The argument of the Dirac \(\delta\)-function allows to define the threshold frequency of absorption \(\Omega_{00}\).

**CONCLUSION**

In this work, we have studied the direct interband transitions quantum dot superlattice. We obtained the analytical expressions for the light interband absorption coefficient and threshold frequency of absorption geometrical size of quantum dot superlattice. We studied the dependence of absorption threshold frequency on quantum dot superlattice size. According to the results obtained from the present work, it is deduced that the quantum dot superlattice size play important roles in the absorption threshold frequency.
